

**Species boundaries in *Lippia asperrima* and *Lippia turnerifolia* complex (Verbenaceae)**

Leonardo Paz Deble^{1,2} Bárbara Pinheiro Moreira² Hector Alejandro Keller³
Velci Queiroz de Souza⁴

Abstract. Species boundaries in *Lippia asperrima* and *Lippia turnerifolia* complex (Verbenaceae). The specific boundaries of *Lippia asperrima* and *L. turnerifolia* are discussed. *Lippia contermina* is accepted as segregated of *L. asperrima*, while *L. modesta* and *L. Morongii* are rehabilitated of the synonym of *L. turnerifolia*. *Lantana ovata* and *Lippia contermina* var. *hirsuta* are recognized as new synonymies of *Lippia contermina*, whereas *Lippia trachyphylla* is treated as cospecific of *L. modesta*, and *L. asperima* f. *angustifolia* is reduced under *L. Morongii*. All treated species are described and illustrated, and information on taxonomic relationships and morphological limits are discussed. A Dichotomous key for distinguishing the species of *Lippia* sect. *Dioicolippia* is proposed. *Lippia* sect *Dioicolippia* comprises 21 species distributed mainly in southern and central-western Brazil, northeast and northern Argentina, Paraguay and Uruguay.

Keywords: Argentina, Bolivia, Brazil, Conservation, *Dioicolippia*, Paraguay, taxonomy, Uruguay.

Resumo. Limites específicos no complexo de *Lippia asperrima* e *Lippia turnerifolia* (Verbenaceae). Os limites específicos de *Lippia asperrima* e *L. turnerifolia* são discutidos. *Lippia contermina* é reconhecida como distinta de *L. asperrima*, enquanto *L. modesta* e *L. Morongii* são reabilitados da sinonímia de *L. turnerifolia*. *Lantana ovata* e *Lippia contermina* var. *hirsuta* são considerados novos sinônimos de *Lippia contermina*, enquanto *Lippia trachyphylla* é considerada coespecífica de *L. modesta*, e *L. asperima* f. *angustifolia* é reduzida a sinonímia de *L. Morongii*. Todas as espécies tratadas são descritas e ilustradas, sendo inferidas informações sobre relações taxonômicas e limites morfológicos, além de ser proposta chave para a distinção das espécies de *Lippia* sect. *Dioicolippia*. *Lippia* sect. *Dioicolippia* compreende 21 espécies distribuídas principalmente no sul, sudeste e centro-oeste do Brasil, nordeste e norte da Argentina, Paraguai e Uruguai.

Palavras-chave: Argentina, Bolivia, Brasil, Conservação, *Dioicolippia*, Paraguai, taxonomia, Uruguai.

In view of the high number of species and the different morphological groups recognized in *Lippia* Linnaeus (1753: 633), its taxa were grouped into infrageneric categories (Schauer 1847, Grisebach 1866, Briquet 1897, Troncoso 1961, 1974). The section *Dioicolippia* was described by Troncoso (1974) to include nineteen species: *Lippia aberrans* (Briquet, 1904: 1160) Troncoso (1961: 267), *L. angustifolia* Chamisso (1832: 377), *L. asperrima* Chamisso (1832: 215), *L. Arechavaletae* Moldenke (1940: 420), *L. contermina* Briquet (1904: 1157), *L. coriacea* Briquet (1904: 1160), *L. hieraciifolia* Chamisso (1832: 375), *L. intermedia* Chamisso (1832: 378), *L.*

longepedunculata Kuntze (1898: 253), *L. modesta* Briquet (1904: 311), *L. Morongii* Kuntze (1898: 253), *L. phaeocephala* Briquet (1904: 1158), *L. polytricha* Briquet (1904: 1158), *L. Rodriguezii* Moldenke (1940: 426), *L. scaposa* Briquet (1904: 1162), *L. tegulifera* Briquet (1904: 309), *L. trachyphylla* Briquet (1904: 312), *L. tristis* Briquet (1904: 1159) and *L. villafloridana* Kuntze (1898: 253). Subsequently, Troncoso (1975) added *Lippia coarctata* Troncoso (1975: 490) to *Dioicolippia*. Múlgura (2000) revised *Dioicolippia* and reduced the number of valid taxa to fifteen (14 species and a variety), establishing new synonyms for *Lippia asperrima*, *L. hieraciifolia* and *L. turnerifolia*.

Chamisso (1832: 217) and including *L. pumila* Chamisso (1832: 218) in *Dioicollippia*. Salimena & Múlgura (2015) added *Lippia nana* Schauer (1847: 582) to the synonymy of *L. pumila* and this treatment was followed for Brazilian Flora (BFG 2015, 2018, 2021 [2022]). Later, Cardoso et al. (2019) reestablished *Lippia nana* as a distinct taxon from *L. pumila*. More recently, Moreira et al. (2021) described *Lippia crucifera*, including it in *Dioicollippia*. In one last contribution, Moreira et al. (2022) rehabilitated *Lippia Rodriguezii* from the synonymy of *L. asperrima*, and currently, 17 taxa are recognized for *Lippia* sect. *Dioicollippia* (IBODA 2022+). *Lippia* sect. *Dioicollippia* comprises dioecious subshrubs with slender or tuberose rhizomes, flowers arranged in subglobose, ovoid or hemispherical capituliform spikes, forming axillary racemes or, more rarely, terminal bracteiform racemes, and corolla yellow or yellow-orange (Múlgura 2000).

During the analysis of exsiccates of species of *Lippia*, it was evidenced a problematic to recognize the limits between *Lippia asperrima* and *L. turnerifolia*, two taxa described by Chamisso (1832) that have a wide geographic distribution, phenotypic plasticity, extensive list of synonyms and, with often have their names assigned to different species of *Lippia*. In view of the restriction to the recognition of species based solely on the analysis of dry material, field trips were carried out in southern Brazil, Uruguay, northeastern Argentina and southern Paraguay to search for type locations and identify different populations that represent the morphologic variations of these taxa. With the data obtained, four species previously recognized as synonyms are re-established as valid species, new synonyms are recognized within the section *Dioicollippia*, and an updated key for the species of *Lippia* sect. *Dioicollippia* is proposed.

Results

Lippia asperrima Chamisso, Linnaea 7: 215. 1832. Typus: BRAZIL. “E Brasilia tropica misit Sellow” (holotype: B destroyed). Lectotypus (designated by Múlgura 2000: 248): BRAZIL. Rio Grande do Sul: ebenda von Alegrete über die Misiones durch den nördlichen Teil des Staates nach Porto Alegre, May-November 1826, F. Sellow s.n. [=3743] (K000470912 image seen! isolectotypi P00713661 image seen! HAL0098269 image seen!).

Dioecious subshrubs, 30–80 cm high, with long rhizomes and 2–5 branches, branches 2–4-branched at proximal third, with 2–6 sterile nodes with internodes 1–7 cm long, and up to 10 fertile nodes with internodes 3–7 cm long; densely covered by pedicellate glandular trichomes 240–480 µm long, with a 3–6-celled foot and strigose trichomes with verrucose wall and 400–800 µm long. Leaves opposite, sessile or shortly petiolate; blades elliptic or oblanceolate, 2.5–11 × 1–4 cm, apex acute, base attenuate, chartaceous, concolorous, abaxial surface with strigose trichomes scattered, pedicellate glandular trichomes scarce accompany the veins, scabrous trichomes few, restricted to the veins, adaxial surface with strigose trichomes scattered and mixed with pedicellate glandular trichomes; leaf margin irregularly toothed, up to 12 teeth on each side, acute or obtuse, spaced, slightly revolute, the most basal leaves smaller and ovate or broadly oblong. Synflorescence in axillary racemes, arranged on up to 10 fertile nodes. Inflorescence pedunculate, on capituliform racemes; peduncles 3.5–8 cm long, with of equal length or a few shorter or a few longer than the leaf corresponding to the fertile node, with dense glandular and non-glandular strigose trichomes. Staminate spike broadly ovate, 8–10 × 6–10 mm. Bracts lanceolate, apex acuminate, adaxial surface with dense strigose trichomes mixed with pedicellate trichomes; the outermost 3.5–5 × 1–2 mm, the innermost 4–5 × 1–1.5 mm. Staminate flowers lacking a calyx; corolla 4–5 mm long, light yellow, infundibuliform, tube hairy on the distal half, stamens with anthers visible at apex of the throat; anthers 0.2–0.3 mm long, pollen yellow; pistil absent. Pistillate spike ovate, 6–10 × 6–10 mm. Bracts lanceolate or oblanceolate, apex acute, adaxial surface with dense strigose trichomes mixed with pedicellate glandular trichomes; the outermost 3–4.5 × 1.5–2 mm, the innermost 4–6 × 1.5–2 mm. Pistillate flowers with diminutive calyx, bilobed, ca. 0.3 mm long, externally sericeous; corolla 4–5 mm long, light yellow, infundibuliform, tube hairy on the distal half; stamens absent; gynoecium 2–2.5 mm long; ovary ca. 0.5 mm long. Fruit a schizocarp, globose or depressed-globose, 1.2–2 × 1.2–2 mm long.

Nomenclatural notes— Chamisso (1832) not provided a precise indication of the place of collection and he mentioned in the protologue *<E Brasilia tropica misit Sellow>*. The lectotype chosen by Múlgura (2000: 248) deposited at K herbarium has the following information *<Reliquiae d. Sello>* *<Ex Museo botanico Berolinensi. 15 Nov 1907>*, the number 3743 is handwritten. According to Urban (1893) in his study of Sellow's itineraries in Brazil and Uruguay, the collection Sellow 3743 was made *<ebenda von Alegrete über die Misiones durch den nördlichen Teil des Staates nach Porto Alegre, V-XI 1826>*. At P and HAL Herbaria there are materials with the indication *Sellow s.n.* which supposedly represent duplicates of the material at K Herbarium.

Discussion— *Lippia asperrima* is very similar to *L. Morongii* and *L. turnerifolia*, all these species share similar leaves, inflorescences and flowers. However, *L. asperrima* can be distinguished from *L. turnerifolia* by its bigger size (30–80 cm vs. 5–40 cm), by its slender and long rhizomes (vs. short and tuberose rhizome), by its glandular trichomes with 3–5-celled foot, 240–450 µm long (vs. glandular trichomes 2–3-celled foot, 160–240 µm long), covering abundantly stems and peduncles (vs. absent on stems and scarce on peduncles) and by its globose or depressed-globose fruits, 1–2 mm long (vs. ovoid-turbinate fruits, 3.5–5 mm long). *Lippia asperrima* differs from *L. Morongii* by its glandular trichomes with 3–5-celled foot, 240–480 µm long (vs. glandular trichomes 2–3-celled foot, 90–180 µm long), covering abundantly stems and peduncles

Figure 1. *Lippia asperrima*. A. Basal part of the plant showing the rhizome. B. Distal part showing the flowering branch. C. Leaf, abaxial and adaxial view. D. Staminate spike. E. Staminate flower. F. Outer bract of staminate spike. G. Inner bract of staminate spike. H. Pistillate spike. I. Pistillate flower. J. Outer bract of pistillate spike. K. Inner bract of pistillate spike. L. Fruit. M. (vs. absent or scarce on stems and absent or scarce on peduncles), by its leaves acute or obtuse at apex, with blades elliptic or oblanceolate, 2.5–11 × 1–4 cm (vs. acuminate at apex, with blades linear-elliptic, elliptic-lanceolate or linear-oblanceolate, 3–10 × 0.5–1.5 cm); leaf margin irregularly toothed, up to 12 teeth on each side, acute or obtuse, spaced (vs. leaf margin irregularly serrated in its distal half, up to 8 teeth on each side, small, acute, appressed) and by its globose or depressed-globose fruits, 1–2 mm long (vs. broadly ovoid fruits, 2–2.5 mm long).

Lippia contermina Briquet, Bulletin de l'Herbier Boissier, ser. 2, 4: 1157. 1904. Typus: PARAGUAY. “in dumeto pr. Fort Lopez, Sept., n. 912 (...) in valle fluminis Y-aca, in campo pr. Valensuela, Jan., n. 6941”. Lectotypus (designated by Troncoso 1961: 270): PARAGUAY. Cordillera: Valenzuela, “in valle fluminis Y-aca, in campo pr. Valensuela [Valenzuela]”, ♀, January 1900, E. Hassler 6941 (G00307900 image seen! islectotypus BM000098690 image seen!).

= *Lippia contermina* var. *hirsuta* Moldenke, Phytologia 51 (2): 162. 1982. Typus: PARAGUAY. Paraguarí “between Caapucú and Villaflorida, Paraguay, in a dry field about 8 km from Villaflorida” ♂, 15 September 1980, J. Fernandez Casas & J. Molero 3660 (holotypus K not seen, isotypus NY00064121 image seen!). **syn. nov.**

Dioecious subshrubs, 20–50 cm high, with tuberose rhizome from which several branches depart, branches unbranched or 2-branched at proximal third, erect-ascending, with 2–5 sterile nodes with internodes 1–4 cm long, and 2–3 fertile nodes with internodes 2.5–5 cm long; densely covered by pedicellate glandular trichomes with a 3–6-celled foot and 280–520 µm long, and strigose trichomes with verrucose wall and 650–1.000 µm long. Leaves opposite, shortly petiolate, petioles up to 1 cm long; blades obovate, broadly elliptic or oblanceolate, 2.5–7 × 1.5–4 cm, apex obtuse or rounded, base attenuate, chartaceous, concolorous or slightly discolored, abaxial surface with strigose trichomes scattered, pedicellate glandular trichomes scarce accompany the veins, scabrous

trichomes few, restricted to the veins, adaxial surface with scabrous trichomes scattered and mixed with pedicellate glandular trichomes; leaf margin irregularly toothed, up to 8 teeth on each side, acute or obtuse, spaced, slightly revolute, the most basal smaller and broadly obovate or nearly circular. Synflorescence in axillary racemes, arranged on 2–3 fertile nodes. Inflorescence pedunculate, on capituliform racemes; peduncles 4.5–10 cm long, with equal length or up to twice as long that the leaf corresponding to the fertile node, with dense glandular and non-glandular strigose trichomes. Staminate spike hemispheric or broadly campanulate, 4–7 (9) × 3.5–7 mm. Bracts linear-lanceolate to lanceolate, apex long acuminate, the innermost revolute at apex, adaxial surface with dense strigose trichomes mixed with pedicellate glandular trichomes; the outermost 4–7 × ca. 1 mm, the innermost 3–4 × 1–1.5 mm. Staminate flowers lacking a calyx; corolla 1.5–3.5 mm long, light yellow to orange, infundibuliform, tube glabrous or with few hairs on the distal half, stamens with anthers visible at apex of the throat; anthers 0.15–0.2 mm long, pollen yellow; pistil absent. Pistillate spike hemispheric or campanulate, 4–7 × 3–6 mm. Bracts linear-lanceolate to lanceolate, apex long acuminate, the innermost revolute at apex, adaxial surface with dense strigose trichomes mixed with pedicellate glandular trichomes; the outermost 4–6 × ca. 1 mm, the innermost 4–6 × 1.5–2 mm. Pistillate flowers with diminutive calyx, bilobed, ca. 0.1 mm long, externally sericeous; corolla 2–4 (6) mm long, light yellow or greenish-yellow, infundibuliform, tube glabrous or with few hairs on the distal half; stamens absent; gynoecium 1.5–2 mm long; ovary ca. 0.5 mm long. Fruit a schizocarp, globose or broadly ovoid, 1.5–2 × 1–1.6 mm long.

Nomenclatural notes I— The type of *Lantana ovata* differs from *Lippia contermina* by the larger diameter of the inflorescence (up to 9 mm) and by the outer bracts, acutes and with a non-reflex apex (vs. acuminate, at apex reflexes) and by the female flowers up to 6 mm long (vs. 2–4 mm); however, the other morphological characteristics demonstrate that *Lantana ovata* and *Lippia contermina* are conspecific.

Nomenclatural notes II— The type of *Lippia contermina* var. *hirsuta* slightly differs from the type of *L. contermina* by its longer internodes and branches and leaves with abundant strigose trichomes. However, no additional morphological features were observed that could justify both taxa as distinct.

Discussion— *Lippia contermina* is easily recognized by its inflorescences born on longer

peduncles and in small spikes, hemispherical or campanulate in shape, and by its outermost bracts linear-lanceolate, with long acuminate and reflexes apices. This species is closely related to *L. modesta*; however, differs by its cushion-like habit, with erect-ascending branches (vs. diffuse habit, with ascending-prostrate branches), by its pedicellate glandular trichomes abundant on stems and peduncles, 280–520 µm long and 3–6-celled foot (vs. pedicellate glandular trichomes scarce to abundant on stems and peduncles, 90–180 µm long, and 2–3-celled foot), and by its smaller spikes with outermost bracts linear-lanceolate, with long acuminate and reflexes apices. *Lippia contermina* was considered synonym of *L. asperrima* by Múlgura (2000); however, the species is easily separated by its cushion-like habit, shape of leaves, and mainly by the shape of inflorescences and smaller size of staminate and pistillate flowers.

Lippia modesta Briquet, Annaire du Conservatoire & du Jardin Botaniques de Genève 7-8: 311. 1904. Typus: PARAGUAY. Guairá: “Plaine située à l’ouest du Cerro-Peron [Perõ], près de Pirayu, juin 1874 (n. 1036c)” ♂ and ♀, June 1874, B. Balansa 1036c (holotypus P00713710 image seen! isotypus SI003557!)

= *Lippia trachyphylla* Briquet, Annaire du Conservatoire & du Jardin Botaniques de Genève 7-8: 312. 1904. Typus: PARAGUAY. Cordillera: “Bords argileux près de l’Y-acan-guazu, près de Valenzuela, novembre 1882, tiges couchées, fleus dún rose violet (n. 4626)” ♀, B. Balansa 4626 (holotypus G00307837 image seen! isotypus P00166258 image seen!). **syn. nov.**

Dioecious subshrubs, 10–40 cm high, with tuberous rhizome from which 3–8 branches depart and several branches, branches unbranched or 2-branched at proximal third, prostrate or prostrate-ascending, with 1–4 sterile nodes with internodes 1–4 cm long, and 1–3 fertile nodes with internodes 1.5–3 cm long; with abundant strigose trichomes with verrucose wall and 750–1.200 µm long, and scarce to dense pedicellate glandular trichomes 90–180 µm long, with a 2–3-celled foot, ad often hidden by the strigose trichomes. Leaves opposite, shortly petiolate, petioles up to 1 cm long; blades obovate, obovate-elliptic or oblanceolate, 1–5 × 0.5–2.5 cm, apex obtuse or rounded, base attenuate, chartaceous, concolorous or slightly discolors; abaxial surface with strigose trichomes scattered, pedicellate glandular trichomes absent or scarce accompany the veins,

Figure 3. *Lippia modesta*. A. Plant, showing part of rhizome. B. Fertile staminate node, showing a staminate spike, pedicel and leaf. C. Leaf, abaxial and adaxial view. D. Staminate flower. E. Staminate bracts. F. Pistillate spike. G. Pistillate flower. H. Pistillate bracts. I. Pistil. J. Fruit with dry corolla. K. Glandular trichome. L. Strigose trichome. M. Sericeous trichome. N. Hirsute trichome from abaxial surface of the leaf. All from Deble & Moreira 17327.

sericeous trichomes absent or abundant, with smooth wall and 70–120 µm long, adaxial surface with scabrous trichomes abundant, 240–500 µm long; leaf margin irregularly toothed, up to 6 teeth on each side, acute or obtuse, spaced, slightly revolute, the most basal smaller and broadly obovate or nearly circular. Synflorescence in axillary racemes, arranged on 1–3 fertile nodes. Inflorescence pedunculate, on capituliform racemes; peduncles 1.5–5 cm long, with of equal length or up to twice as long that the leaf corresponding to the fertile node, with abundant strigose trichomes and scarce pedicellate glandular-trichomes. Staminate spike campanulate to hemispheric, 5–10 × 3.5–8 mm. Bracts lanceolate, elliptic-lanceolate or linear-elliptic, apex acuminate, adaxial surface with dense strigose trichomes mixed with pedicellate glandular trichomes; the outermost 4–5 × ca. 1 mm, the innermost 3–4.5 × 0.7–1.5 mm. Staminate flowers lacking a calyx; corolla 3.5–4.5 mm long, light yellow, infundibuliform, tube glabrous or with few hairs on the distal half, stamens with anthers visible at apex of the throat; anthers ca. 0.2 mm long, pollen yellow; pistil absent or rudimentary. Pistillate spike campanulate become ovoid at fruit maturity, 5–10 × 3–6 mm. Bracts lanceolate to elliptic, apex acuminate, adaxial surface with dense strigose trichomes mixed with pedicellate glandular trichomes; the outermost 4–5 × 1–1.5 mm, the innermost 4–5 × 1.5–2 mm. Pistillate flowers with diminutive calyx, bilobed, ca. 0.1 mm long, externally sericeous; corolla 3–4 mm long, light-yellow or greenish-yellow, infundibuliform, tube glabrous or with few hairs on the distal half; stamens absent; gynoecium 1.5–2 mm long; ovary ca. 0.5 mm long. Fruit a schizocarp, globose or broadly ovoid, 1–1.5 × 1–1.5 mm long.

Nomenclatural notes— The type of *Lippia trachyphylla* displays scarce sericeous trichomes on abaxial surface of leaves and the inflorescence born in short peduncles when compared with the type of *L. modesta*; however, the analysis of specimens show variation in the abundance and type of trichomes, and inflorescence peduncle length, not being possible to distinguish between both taxa.

Discussion—*Lippia modesta* is easily recognized by its smaller habit and small size of its inflorescences. The species was recognized as synonym of *L. turnerifolia* by Múlgura (2000); nevertheless, *L. modesta* is easily segregated from *L. turnerifolia* by its smaller staminate spikes ($5–10 \times 3.5–8$ mm vs. $8–14 \times 8–12$ mm), smaller pistillate spikes ($5–10 \times 3–6$ mm vs. $10–15 \times 8–14$ mm) and mainly by size and shape of fruits (globose or broadly ovoid, $1–1.5 \times 1–1.5$ mm vs. ovate-turbinate, $3.5–5 \times 3–4$ mm). *Lippia modesta* is closely related to *Lippia contermina* and *L. Morongii*. However, differs from *L. Morongii* by its smaller habit (10–40 cm vs. 30–100 cm) by its prostrate or ascending-prostrate branches (vs. erect or ascending-erect), by its leaves with obovate, obovate-elliptic or oblanceolate blades, $1–5 \times 0.5–2.5$ cm (vs. leaves with linear-elliptic, elliptic-lanceolate or oblanceolate blades, $3–10 \times 0.5–1.5$ cm), obtuse or rounded at apex (vs. acuminate). From *Lippia contermina* differs by its diffuse habit, with ascending-prostrate branches (vs. cushion-like habit, with erect-ascending branches), by its pedicellate glandular trichomes scarce to abundant on stems and peduncles, 90–180 μm long, and 2–3-celled foot (vs. pedicellate glandular trichomes abundant on stems and peduncles, 280–520 μm , and 3–6-celled foot, and by its spikes with outermost bracts lanceolate, elliptic-lanceolate, elliptic or linear-elliptic, straight at apex (vs. linear-lanceolate, with long acuminate and reflexes apices).

Lippia Morongii Kuntze, Revisio Generum Plantarum 3 (3): 253. 1898. Typus: PARAGUAY. Without specific department [Boquerón or Presidente Hayes]: Pilcomayo [Pilkumayu] river, ♂ and ♀ 9 January 1890, T. Morong 860 (holotypus NY00137788 image seen! isotypi BM000098703 image seen! Nomenclatural notes— The type of *Lippia asperrima* f. *angustifolia* slightly differs from the type of *L. Morongii* by its more thickened rhizomes and abundant glandular trichomes on peduncles; however, this morphologic pattern was observed in specimens of *L. Morongii* with growth in more sandy and dry environments.

Discussion— *Lippia Morongii* was treated as synonym of *L. turnerifolia* by Múlgura (2000) and this criterion was followed by all later authors (e.g. Múlgura 2012, BFG 2015, 2018, 2021 [2022], IBODA 2022+). However, *Lippia Morongii* distinguishes from *L. turnerifolia* by its bigger habit (30–100 cm vs. 5–30 cm high), with long and slender rhizomes (vs. short and tuberous rhizome), by its erect-ascending or erect branches (vs. prostrate or prostrate-ascending branches), by its inflorescence with peduncles covered by scarce and strongly appressed trichomes, 350–700 µm long (vs. abundant strigose trichomes, non-appressed, 900–1.400 µm long), and mainly by its smaller fruits, completely hidden by calyx (broadly ovoid, 2–2.5 × 2–2.5 mm long vs. ovate-turbinata, 3.5–5 × 3–4 mm).

Dioecious subshrubs, 5–30 cm high, with tuberous rhizome from which 2-several branches depart, branches unbranched or 2-branched in its distal half, prostrate or prostrate-ascending, with 1–3 sterile nodes with internodes 1–3 cm long, and 1–3 fertile nodes with internodes 0.5–2.5 cm long; with abundant strigose trichomes with verrucose wall and 900–1.400 µm long, glandular trichomes absent. Leaves opposite, sessile or shortly petiolate, petioles up to 0.5 cm long; blades oblong, lanceolate or elliptic 1.5–4 × 0.5–2 cm, apex obtuse or rounded, base attenuate, chartaceous, concolorous or slightly discolors; abaxial surface with strigose trichomes scattered, pedicellate glandular trichomes absent, sericeous trichomes absent or few, with smooth wall and 70–120 µm long, adaxial surface with scabrous trichomes abundant, 350–1.000 µm long; leaf margin slightly revolute, irregularly toothed, up to 6 teeth on each side, acute or obtuse, spaced, the most basal smaller and broadly obovate or nearly circular. Synflorescence in axillary racemes, arranged on 1–3 fertile nodes. Inflorescence pedunculate, on capituliform racemes; peduncles 0.5–3.5 cm long, with ca. of ½ of the length that the leaf corresponding to the fertile node, with abundant strigose trichomes, 1.100–1.600 µm long and scarce pedicellate glandular-trichomes, 180–240 µm long, with a 2–3-celled foot. Staminate spike broadly campanulate, 8–14 × 8–12 mm. Bracts lanceolate or elliptic-lanceolate, apex acute, adaxial surface with dense strigose trichomes; the outermost 5–7 × 1.5–2 mm, the innermost 5–7.5 × 1–1.5 mm. Staminate flowers with a diminutive calyx; corolla 4.5–6.5 mm long, golden-yellow, infundibuliform, tube hairy on the distal half, stamens with anthers visible at apex of the throat; anthers ca. 0.3 mm long, pollen yellow; pistil absent or rudimentary. Pistillate spike campanulate become broadly ovoid at fruit maturity, 10–15 × 8–14 mm.

Figure 5. *Lippia turnerifolia*. A. Plant, showing the rhizome. B. Fertile staminate node, showing a staminate spike, pedicel and leaf. C. Leaf, abaxial and adaxial view. D. Staminate flower. E. Outer bract staminate spike. F. Inner bract of staminate spike. G. Pistillate spike. H. Pistillate flower. I. Bracts of pistillate spike. J. Fruit. K. Glandular trichome. L. Strigose trichome from pedicel. M. Strigose trichome from adaxial surface of the leaf. A-F, K-M from Deble & Moreira 21904. G-J from Keller et al. 11631.

Bracts ovate-lanceolate to elliptic, apex acute, adaxial surface with dense strigose trichomes; the outermost $5.7 \times 1.5\text{--}2.5$ mm, the innermost $5.5\text{--}7.5 \times 1.5\text{--}2$ mm. Pistillate flowers with diminutive calyx, bilobed, ca. 0.2–0.3 mm long, externally sericeous; corolla 5–8 mm long, golden-yellow, infundibuliform, tube hairy on the distal half; stamens absent; gynoecium 2–3 mm long; ovary ca. 0.8 mm long. Fruit a schizocarp, ovate-turbinate, $3.5\text{--}5 \times 3\text{--}4$ mm.

Nomenclatural notes I— The type of *L. turnerifolia* var. *angusta* is more pilose and with narrowed leaves. During the analysis of herbarium exsiccates, it was possible to verify that Múlgura linked specimens that present this morphological pattern under the name *Lippia turnerifolia* var. *polytricha*. *Lippia polytricha* is a distinct species, with ovate or ovate-oblong leaves, densely covered by hirsute trichomes, absence of glandular trichomes, and smaller and broadly ovate fruits (see Moreira et al. 2021).

Nomenclatural notes II— The type of *L. turnerifolia* var. *sessilifolia* differs from the type of *L. turnerifolia* by its apparently erect branches. However, no additional features were observed that could separate both taxa.

Discussion— *Lippia turnerifolia* is easily recognized by its reduced habit, by its prostrate or prostrate-ascending branches, by its short internodes, by its bigger staminate and pistillate spikes and mainly by its ovate or ovate-turbinate fruits, with $3.5-5 \times 3-4$ mm. *Lippia turnerifolia* is more closely related to *Lippia coarctata*, however it differs by its leaves more rigid and lacking glandular trichomes, by its inflorescence with peduncles covered by abundant strigose trichomes, non-appressed, 900–1.400 µm long (vs. peduncles with scarce strigose trichomes strongly appressed, 500–800 µm long) and by its bigger staminate and pistillate flowers. *Lippia turnerifolia* distinguishes from *L. Morongii* by its smaller habit (5–30 cm vs. 30–100 cm), with short and tuberous rhizome (vs. long and slender rhizomes), by its prostrate or prostrate-ascending branches (vs. erect-ascending or erect branches), (vs. peduncles covered by scarce and strongly appressed trichomes, 350–700 µm long), and mainly by its bigger fruits (ovate or ovate-turbinate, $3.5-5 \times 3-4$ mm vs. ovate, $2-2.5 \times 2-2.5$ mm long). *L. turnerifolia* differs from *L. modesta* by its bigger staminate spikes ($8-14 \times 8-12$ mm vs. $5-10 \times 3.5-8$ mm), bigger pistillate spikes ($10-15 \times 8-14$ mm vs. $5-10 \times 3-6$ mm) and mainly by size and shape of fruits (ovate-turbinate, $3.5-5 \times 3-4$ mm vs. globbose or broadly elliptic, $1-1.5 \times 1-1.5$ mm).

Doubtful taxa

Lippia phaeocephala Briquet, Bulletin de l'Herbier Boissier ser. 2, 4: 1158. 1904. Typus: PARAGUAY. “Suffrutex 0,4-0,5 m. altus, petala citrina, in valle fluminis Y-aca, in campo pr. Chololo, Dec., n. 6798a; suffrutex 0,3-0,6 m. altus, petala aurantiaca, prope Concepcion, in campo argilloso, Sept. n. 7456.” Lectotypus (designated by Troncoso 1961: 275): PARAGUAY. Cordillera: Chololo, “in valle fluminis Y-aca, in campo pr. Chololo” Dec. 1900, E. Hassler 6798a (G00634744 not seen).

Lippia phaeocephala was considered a synonym of *L. asperrima* by Múlgura (2000) and this treatment was followed in later works (Múlgura 2012, FBO 2015, FBO 2018). During the analysis of the syntype *E. Hassler* 7456 deposited at BM and NY herbaria, it was confirmed that this voucher corresponds to *L. asperrima*, as previously mentioned by Troncoso (1961: 275-276): “*Briquet describe su especie basándose en dos sintipos: Hassler 6798a y 7456. Estos ejemplares, del Herbario de Ginebra, son una mezcla de dos especies diferentes. He debido seleccionar como lectotipo Hassler 6798a, a pesar de no ser el que figura en los fototipos de la serie del Museo de Chicago, pues el otro ejemplar, Hassler 7456, parece pertenecer a una especie ya conocida, *L. asperrima* Cham.*”. Troncoso (1961: 276) proposed lectotypification and amendment for this species: “*Como la descripción de Briquet se basa en los dos ejemplares, el lectotipo requiere una redescipción*”. However, it was not possible to locate the lectotype chosen by Troncoso. It is still possible to show that the illustration presented by Troncoso (1961: 277) is a distinct taxon from *L. asperrima*. Thus, in the absence of type analysis, we prefer to consider the species as a doubtful taxon.

Lippia turnerifolia* var. *normalis Kuntze, Revisio Generum Plantarum 3 (3): 253. 1898. Typus: ARGENTINA/BOLIVIA: Jujuy, October 1892, O. Kuntze s.n. (holotype NY? isotype? US03198705 image seen!).

It was not possible to confirm whether the material deposited at the US herbarium here mentioned as a possible isotype is an original material from *L. turnerifolia* var. *normalis*. However, the location indication coincides with that indicated in the protologue by Kuntze (1898: 253). The analysis of this exsiccate indicates that it is *Lippia modesta*. Thus, it is probable that *L. modesta* var. *normalis* is a synonym of *Lippia modesta*.

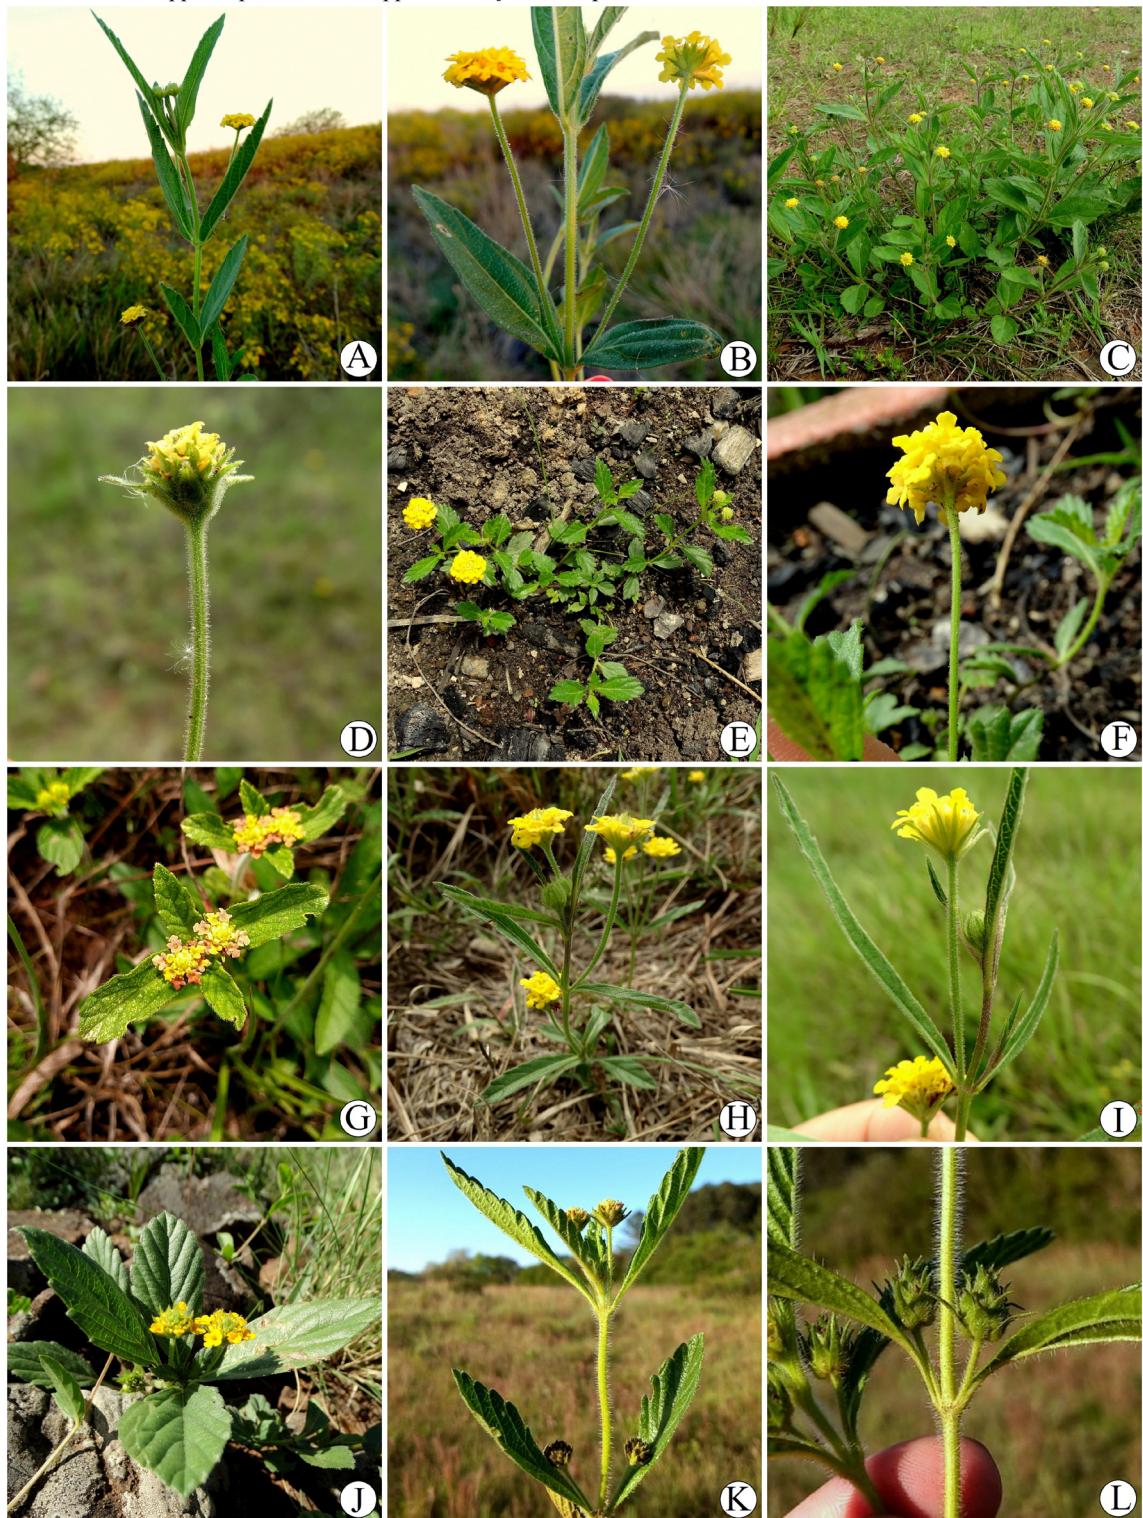

Figure 6. *Lippia asperrima* (A-B) A. Distal part showing the flowering branch. B. Fertile node showing leaf, pedicel and staminate spike. *Lippia contermina* (C-D) C. Habit. D. Staminate spike showing apex of the pedicel. *Lippia modesta* (E-F-G) E. Habit. F. Staminate spike, showing apex of the pedicel. G. Specimen with pattern of *L. trachiphylla*. *Lippia Morongii* (H-I) H. Distal part showing the flowering branch. I. Fertile node showing leaf, pedicel and staminate spike. *Lippia turnerifolia* (J-K-L) J. Staminate individual with dwarf habit. K. Distal part showing the flowering branch.. L. Fertile node showing leaf, pedicel and pistillate spike.

Key to distinguish the species of Lippia sect. Dioicolippia

1. Fertile nodes with bracteiform leaves. Sinflorescence borne in terminal bracteiform racemes 2
– Fertile nodes with developed leaves. Sinflorescence borne in axillar foliose racemes 3
2. Sterile nodes 2–4 concentrate in the proximal third of the plant *Lippia hieraciifolia*
– Sterile nodes 8–12 (or more) extending in the proximal half of the plant *Lippia angustifolia*
3. Inflorescence much exceeding the branches, with peduncles 2–4 times longer than the leaf corresponding to the fertile node 4
– Inflorescence not exceeding the branches (exceptionally slightly exceeding: *L. contermina*), with peduncles shorter or up to two times longer than the leaf corresponding to the fertile node 6
4. Subshrubs with slender rhizomes, branches erect or erect-ascending, 30–40 cm long. Leaves linear-elliptic or linear-oblong, blades with margin entire *Lippia aberrans*
– Subshrubs with short and tuberous rhizomes, branches ascending or prostrate, 5–20 cm long. Leaves ovate, ovate-oblong or elliptic, blades with margin entire or toothed 5
5. Leaves with margin entire, rarely provide of 1–2-teeth on each side *Lippia longepeduculata*
– Leaves with margin toothed, with 3–8-teeth on each side *Lippia villafloridana*
6. Dwarf subshrubs (usually less than 10 cm high), with few and very short internodes and 1–2 fertile nodes 7
– Subshrubs or shrubs with 10–170 cm high, with 2 or more fertile nodes 10
7. Glandular trichomes abundant on stems, peduncles and bracts 8
– Glandular trichomes absent or few, restricted to the peduncles and bracts 9
8. Leaves elliptic or ovate, margin irregularly toothed, base cuneate. Fruits 3–4.5 mm. Stony grasslands in Campos regions of Río de La Plata Grasslands (Uruguay and Rio Grande do Sul [Brazil]) *Lippia coarctata*
– Leaves obovate, oblanceolate or spathulate, margin crenulate base long attenuate (exceptionally rounded in young leaves). Fruits 2–3 mm. Cerrados and Campos Rupestres in central Brazil (Distrito Federal, Goiás and Minas Gerais) *Lippia nana*
9. Leaves with adaxial surface of the blade covered by strigose pubescence, with the trichomes applied to the blade, 0.5–1.2 mm long *Lippia turnerifolia*
– Leaves with adaxial surface of the blade covered by hirsute pubescence, with the trichomes erect or ascending, 1.4–3 mm long *Lippia crucifera*
10. Leaves usually ascending or erect, sometimes applied to the stem, with rounded, truncated, subauriculate or cordate blades 11
– Leaves patent (exceptionally the most distal ascending), with attenuate or cuneate blades (rarely rounded at the bases, so leaves notably patent) 15
11. Leaves with crenulate margins along their entire length, veins well pronounced, adaxial surface bullate *Lippia Sandwithiana*
– Leaves with entire or few toothed margins, only the principal veins pronounced 12
12. Leaves 3–6.5 cm long *Lippia coriacea*
– Leaves 0.5–3 cm long 13
13. Leaves ovate, apex acute or acuminate, base cordate. Fruits with ca. 2 mm *Lippia tegulifera*
– Leaves lanceolate or oblong-lanceolate, apex slightly acute, base subauriculate or truncate. Fruits with ca. 3–4 mm 14
14. Sterile nodes 5–10 or more, fertile nodes along of distal half of the plant. Internodes shorter than the leaves. Leaves discolored by presence of abundant sericeous trichomes on abaxial surface of the blade *Lippia Arechavaletae*
– Sterile nodes 2–4 (rarely more), fertile nodes in the distal third of the plant. Internodes longer than the leaves. Leaves concolorous or slightly discolored, sericeous trichomes when present restrict to the margins, veins or young leaves *Lippia pumila*
15. Leaves discolored by presence of abundant sericeous trichomes on abaxial surface of the blade; blades with margin regularly serrate provides of 16–24 teeth on each side *Lippia Rodriguezii*
– Leaves concolorous or slightly discolored, sericeous trichomes when present restrict to the margins and veins; blades with margin irregularly toothed provides of up to 12 teeth on each side 16

16. Inflorescence with peduncles with abundant strigose or hirsute trichomes, 1.1–3.2 mm long. Fruits ovate-turbinate, 3–5 mm long, with its distal part visible above the calyx 17
 – Inflorescences with peduncles with scarce strigose trichomes, up to 1 mm long. Fruits depressed-globose, globose or broadly ovoid, 1–3 mm long, completely hidden by the calyx 18
17. Leaves attenuate at the base. Blades with adaxial surface covered by strigose pubescence, with trichomes applied to the blade, 0.5–1.2 mm long *Lippia turnerifolia*
 – Leaves cuneate or rounded at the base. Blades with adaxial surface covered by hirsute pubescence, with trichomes ascending or erect-ascending, 1.4–3.2 mm long *Lippia polytricha*
18. Leaves with margin entire or with 1–4-teeth on each side *Lippia tristis*
 – Leaves with margin irregularly toothed provides of 6–12 teeth on each side 19
19. Plants provide of long horizontal rhizomes at the base 20
 – Plants provide of tuberous rhizome at the base 21
20. Leaves elliptic or oblanceolate, 2.5–11 × 1–4 cm, acute or obtuse at apex, with margin irregularly toothed, up to 12 teeth on each side, spaced. Pedicellate glandular trichomes with 240–450 µm long, covering stems, peduncles and leaves *Lippia asperrima*
 – Leaves linear-elliptic, elliptic-lanceolate or linear-oblanceolate, 3–10 × 0.5–1.5 cm, acuminate at apex, with margin irregularly serrated in its distal half, up to 8 teeth on each side, small, acute, appressed. Pedicellate glandular trichomes 90–180 µm long, absent or scarce on stems and peduncles, and absent in leaves *Lippia Morongii*
21. Plants with a cushion-like habit. Pedicellate glandular trichomes abundant, 280–520 µm long. Spikes with outermost bracts with long acuminate and reflexed apices *Lippia contermina*
 – Plants with diffuse habit. Pedicellate glandular trichomes scarce to abundant, 90–180 µm long. Spikes with outermost bracts with acute and straight apices *Lippia modesta*
