Abstract

In this paper, we introduce a new class of bivariate distributions called the bivariate exponentiated extended Weibull distributions. The model introduced here is of Marshall- Olkin type. This new class of bivariate distributions contains several bivariate lifetime models. Some mathematical properties of the new class of distributions are studied. We provide the joint and conditional density functions, the joint cumulative distribution function and the joint survival function. Special bivariate distributions are investigated in some detail. The maximum likelihood estimators are obtained using the EM algorithm. We illustrate the usefulness of the new class by means of application to two real data sets.

Keywords: Bivariate exponentiated extended Weibull distribution, Joint probability density function, EM-algorithm, Maximum likelihood estimation.
1 Introduction

The Weibull distribution has assumed a prominent position as statistical model for data from reliability, engineering and biological studies (McCool, 2012). The Weibull distribution is a reasonable choice due to its negatively and positively skewed density shapes. However, this distribution is not a good model for describing phenomenon with non-monotone failure rates, which can be found on data from applications in reliability studies. Thus, extended forms of the Weibull model have been sought in many applied areas. As a solution for this issue, the inclusion of additional parameters to a well-defined distribution has been indicated as a good methodology for providing more flexible new classes of distributions.

The class of extended Weibull (EW) distributions pioneered by Gurvich et al. (1997) has achieved a prominent position in lifetime models. Its cumulative distribution function (cdf) is given by

\[ G(x; \lambda, \xi) = 1 - e^{-\lambda H(x; \xi)}, \quad x > 0, \quad \lambda > 0, \quad (1) \]

where \( H(x; \xi) \) is a non-negative monotonically increasing function which depends on the parameter vector \( \xi \). The corresponding probability density function (pdf) is given by

\[ g(x; \lambda, \xi) = \lambda h(x; \xi) e^{-\lambda H(x; \xi)}, \quad x > 0, \quad \lambda > 0, \quad (2) \]

where \( h(x; \xi) \) is the derivative of \( H(x; \xi) \). We emphasize that several distributions could be expressed in the form (1). Table 1 summarizes several of these models. Further, we refer the reader to Nadarajah and Kotz (2005) and Pham and Lai (2007).

In recent years, many authors worked on this class of distributions such as the beta extended Weibull family by Cordeiro et al. (2012), the extended Weibull power series distributions by Silva et al. (2013), the complementary extended Weibull power series class of distributions by Cordeiro and Silva (2014), the Marshall-Olkin extended Weibull family of distributions by Santos-Neto et al. (2014) and the exponentiated extended Weibull power series class of distributions by Tahmasebi and Jafari (2015).

The aim of this paper is to introduce a new bivariate exponentiated extended Weibull (BEEW) family of distributions, whose marginals are exponentiated extended Weibull (EEW) distributions. It is obtained using a method similar to that used to obtain Marshall-Olkin bivariate exponential model (Marshall and Olkin, 1967). The proposed BEEW class of distributions is constructed from three independent EEW distributions using a maximization process. Creating a bivariate distribution with given marginals using this technique is nothing new. The joint cdf can be expressed as a mixture of an absolutely continuous cdf and a singular cdf. The joint pdf of the BEEW distributions can take different shapes and the cdf can be expressed in a compact form. The joint cdf, the joint pdf and the joint survival function (sf) are in closed forms, which make it convenient to use in practice. The new class of bivariate distributions contains as special models the bivariate generalized exponential (Kundu and Gupta, 2009), bivariate generalized linear failure rate (Sarhan et al., 2011), bivariate generalized Gompertz (El-Sherpieny et al., 2013), bivariate exponentiated generalized Weibull-Gompertz (El-Bassiouni et al., 2015), bivariate exponentiated modified Weibull extension (El-Gohary and El-Morshedy, 2015) distributions. This class defines at least 46 \((2 \times 23)\) bivariate sub-models as special cases.

The usual maximum likelihood estimators can be obtained by solving non-linear equations in at least five unknowns directly, which is not a trivial issue. To avoid difficult computation we treat this problem as a missing value problem and use the EM algorithm, which can be implemented more conveniently than the direct maximization process. Another advantage of the EM algorithm is that it can be used to obtain the observed Fisher information matrix, which is helpful for constructing the asymptotic confidence intervals for the parameters. Alternatively, it is possible to obtain approximate maximum likelihood estimators by estimating the marginals first and then estimating the dependence parameter through a copula function, as suggested by (Joe, 1997, Chapter 10), which has the same rate of convergence as the maximum likelihood estimates. This is computationally less involved compared to the MLE calculations. This approach is not pursued here. Although in this paper we mainly discuss the BEEW, many of our results can be easily extended to the multivariate case.

The main reasons for introducing this new class of bivariate distributions are: (i) This class of distributions is an important model that can be used in a variety of problems in modeling bivariate lifetime data. (ii) It provides a reasonable parametric fit to skewed bivariate data that cannot be properly fitted by other distributions. (iii) The joint cdf and joint pdf should preferably have a closed form representation; at least numerical evaluation should be possible. (v) This class contains several special bivariate models because of the general class of Weibull distributions and the fact that the current generalization provides means of its bivariate continuous extension to still more complex situations; therefore it can be applied in modeling bivariate lifetime data.

The rest of the paper is organized as follows. We define the EEW and the BEEW class of distributions in Section 2. Different properties of this family are discussed in this section. The special cases of the BEEW model are considered in Section 3. The EM algorithm

2 The BEEW model

In this section, we introduce the BEEW distributions using a method similar to that which was used by Marshall and Olkin (1967) to define the Marshall-Olkin bivariate exponential (MOBE) distribution.

First, consider the univariate EEW class of distributions with cdf given by

$$F_{\text{EEW}} (x; a, \lambda, \xi) = \left(1 - e^{-\lambda H(x; \xi)}\right)^a, \quad x > 0, \quad a > 0, \quad \lambda > 0. \quad (3)$$

The corresponding pdf is

$$f_{\text{EEW}} (x; a, \lambda, \xi) = a\lambda h(x; \xi) e^{-\lambda H(x; \xi)} \left(1 - e^{-\lambda H(x; \xi)}\right)^{a-1}. \quad (4)$$

From now on a EEW class of distributions with the shape parameter $a$, the scale parameter $\lambda$ and parameter vector $\xi$ will be denoted by EEW($a, \lambda, \xi$). Note that many well-known models could be expressed in the form (3), such as exponentiated Weibull (Mudholkar and Srivastava, 1993), generalized exponential (Gupta and Kundu, 1999), Weibull extension (Chen, 2000), generalized Rayleigh (Surles and Padgett, 2001; Kundu and Raqab, 2005), modified Weibull extension (Xie et al., 2002), generalized modified Weibull (Carrasco et al., 2008) generalized linear failure rate (Saran and Kundu, 2009), generalized Gompertz (El-Gohary et al., 2013), and exponentiated modified Weibull extension (Saran and Apaloo, 2013) distributions.

When $a$ is a positive integer, the EEW model can be interpreted as the lifetime distribution of a parallel system consisting of $a$ independent and identical units whose lifetime follows the EEW distributions.

From now on unless otherwise mentioned, it is assumed that $a_1 > 0$; $a_2 > 0$; $a_3 > 0$ and $\lambda > 0$. Suppose $U_1 \sim \text{EEW}(a_1, \lambda, \xi)$, $U_2 \sim \text{EEW}(a_2, \lambda, \xi)$ and $U_3 \sim \text{EEW}(a_3, \lambda, \xi)$ and they are mutually independent. Here \(\sim\) means follows or has the distribution. Now define $X_1 = \max\{U_1, U_3\}$ and $X_2 = \max\{U_2, U_3\}$. Then, we say that the bivariate vector $(X_1, X_2)$ has a bivariate exponentiated extended Weibull distribution with the shape parameters $a_1$, $a_2$ and $a_3$, the scale parameter $\lambda$ and parameter vector $\xi$. We will denote it by BEEW($a_1, a_2, a_3, \lambda, \xi$). Before providing the joint cdf or pdf, we first mention it how it may occur in practice.

According to Kundu and Gupta (2009), suppose a system has two components and it is assumed that each component has been maintained independently and also there is an overall maintenance. Due to component maintenance, suppose the lifetime of the individual com-
ponent is increased by $U_i$ amount and because of the overall maintenance, the lifetime of each component is increased by $U_3$ amount. Therefore, the increased lifetimes of the two component are $X_1 = \max\{U_1, U_3\}$ and $X_2 = \max\{U_2, U_3\}$, respectively.

We now study the joint cdf of the bivariate random vector $(X_1, X_2)$ in the following theorem.

**Theorem 2.1.** If $(X_1, X_2) \sim \text{BEEW}(\alpha_1, \alpha_2, \alpha_3, \lambda, \xi)$, then the joint cdf of $(X_1, X_2)$ for $x_1 > 0$, $x_2 > 0$, is

$$F_{\text{BE EW}}(x_1, x_2) = \left(1 - e^{-\lambda H(x_1; \xi)}\right)^{\alpha_1} \left(1 - e^{-\lambda H(x_2; \xi)}\right)^{\alpha_2} \times \left(1 - e^{-\lambda H(z; \xi)}\right)^{\alpha_3},$$

where $z = \min\{x_1, x_2\}$.

**Proof.** Since the joint cdf of the random variables $X_1$ and $X_2$ is defined as

$$F_{\text{BE EW}}(x_1, x_2) = P(X_1 \leq x_1, X_2 \leq x_2) = P(\max\{U_1, U_3\} \leq x_1, \max\{U_2, U_3\} \leq x_2) = P(U_1 \leq x_1, U_2 \leq x_2, U_3 \leq \min(x_1, x_2)).$$

As the random variables $U_i$, ($i = 1, 2, 3$) are mutually independent, we directly obtain

$$F_{\text{BE EW}}(x_1, x_2; \alpha_1, \alpha_2, \alpha_3, \lambda, \xi) = F_{\text{BE EW}}(x_1; \alpha_1, \lambda, \xi) \times F_{\text{BE EW}}(x_2; \alpha_2, \lambda, \xi) F_{\text{BE EW}}(z; \alpha_3, \lambda, \xi).$$

Substituting from 3 into 6, we obtain 5, which completes the proof of the theorem.

**Corollary 1.** The joint cdf the BEEW$(\alpha_1, \alpha_2, \alpha_3, \lambda, \xi)$ can also written as

$$F_{\text{BE EW}}(x_1, x_2) = \begin{cases} b_1 & \text{if } x_1 \leq x_2 \\ b_2 & \text{if } x_1 > x_2 \end{cases}$$

where

$$b_1 = \left(1 - e^{-\lambda H(x_1; \xi)}\right)^{\alpha_1} \left(1 - e^{-\lambda H(x_2; \xi)}\right)^{\alpha_2},$$

$$b_2 = \left(1 - e^{-\lambda H(x_1; \xi)}\right)^{\alpha_1} \left(1 - e^{-\lambda H(x_2; \xi)}\right)^{\alpha_2 + \alpha_3},$$

$$c_1 = F_{\text{BE EW}}(x_2; \alpha_2 + \alpha_3, \lambda, \xi) F_{\text{BE EW}}(x_1; \alpha_1 + \alpha_3, \lambda, \xi),$$

$$c_2 = F_{\text{BE EW}}(x_1; \alpha_1, \lambda, \xi) F_{\text{BE EW}}(x_2; \alpha_2, \lambda, \xi),$$

$$c_0 = F_{\text{BE EW}}(x_1; \alpha_1 + \alpha_2 + \alpha_3, \lambda, \xi).$$

The following theorem gives the joint pdf of the random variables $X_1$ and $X_2$ which is the joint pdf of BEEW$(\alpha_1, \alpha_2, \alpha_3, \lambda, \xi)$.

**Theorem 2.2.** If $(X_1, X_2) \sim \text{BE EW}(\alpha_1, \alpha_2, \alpha_3, \lambda, \xi)$ then the joint pdf of $(X_1, X_2)$ for $x_1 > 0$, $x_2 > 0$, is

$$f_{\text{BE EW}}(x_1, x_2) = \begin{cases} f_1(x_1, x_2) & \text{if } 0 < x_1 < x_2 \\ f_2(x_1, x_2) & \text{if } 0 < x_2 < x_1 \\ f_0(x) & \text{if } 0 < x_1 = x_2 = x. \end{cases}$$

where

$$f_1(x_1, x_2) = f_{\text{BE EW}}(x_1; \alpha_1 + \alpha_3, \lambda, \xi) f_{\text{BE EW}}(x_2; \alpha_2, \lambda, \xi)$$

$$= (\alpha_1 + \alpha_3) \alpha_2 \lambda^2 h(x_1; \xi) h(x_2; \xi) \times \left(1 - e^{-\lambda H(x_1; \xi)}\right)^{\alpha_1 + \alpha_3 - 1} \times \left(1 - e^{-\lambda H(x_2; \xi)}\right)^{\alpha_2 - 1} e^{-\lambda H(x_1; \xi) - \lambda H(x_2; \xi)}$$

$$f_2(x_1, x_2) = f_{\text{BE EW}}(x_1; \alpha_1, \lambda, \xi) f_{\text{BE EW}}(x_2; \alpha_2 + \alpha_3, \lambda, \xi)$$

$$= (\alpha_2 + \alpha_3) \alpha_1 \lambda^2 h(x_1; \xi) h(x_2; \xi) \times \left(1 - e^{-\lambda H(x_1; \xi)}\right)^{\alpha_1 - 1} \times \left(1 - e^{-\lambda H(x_2; \xi)}\right)^{\alpha_2 + \alpha_3 - 1} e^{-\lambda H(x_1; \xi) - \lambda H(x_2; \xi)}$$

$$f_0(x) = \frac{\alpha_3}{\alpha_1 + \alpha_2 + \alpha_3} f_{\text{BE EW}}(x; \alpha_1 + \alpha_2 + \alpha_3, \lambda, \xi)$$

$$= \alpha_3 \lambda h(x; \xi) \left(1 - e^{-\lambda H(x; \xi)}\right)^{\alpha_1 + \alpha_2 + \alpha_3 - 1} e^{-\lambda H(x; \xi)}.$$
Thus, the result follows. \qed

The following theorem gives the marginal pdf’s of $X_1$ and $X_2$.

**Theorem 2.3.** The marginal distributions of $X_1$ and $X_2$ are EEW($a_1 + a_3, \lambda, \xi$) and EEW($a_2 + a_3, \lambda, \xi$), respectively.

**Proof.** The marginal cdf for $X_i$ is

$$F_{X_i}(x_i) = P(X_i \leq x_i) = P(\text{max} \{U_i, U_3\} \leq x_i) = P(U_i \leq x_i, U_3 \leq x_i).$$

Since the random variables $U_i$, $(i = 1, 2)$ are mutually independent, we obtain

$$F_{X_i}(x_i) = P(U_i \leq x_i)P(U_3 \leq x_i) = F_{\text{EEW}}(x_i; a_i, \lambda, \xi)F_{\text{EEW}}(x_3; a_3, \lambda, \xi) = F_{\text{EEW}}(x_i; a_i + a_3, \lambda, \xi). \quad (12)$$

From 12, we can derive the pdf of $X_i$ by differentiation.

The BEEW model has both an absolute continuous part and a singular part, similar to Marshall and Olkin’s bivariate exponential model. The joint cdf of $X_1$ and $X_2$ has a singular part along the line $x_1 = x_2$, with weight $\frac{a_3}{a_1 + a_2 + a_3}$, and has an absolutely continuous part on $0 < x_1 \neq x_2 < \infty$ with weight $\frac{a_1 + a_2}{a_1 + a_2 + a_3}$.

Interestingly, the BEEW model can be obtained by using the Marshall-Olkin (MO) copula with the marginals as the EEW distributions. To every bivariate cdf $F_{X_1, X_2}$ with continuous marginals $F_{X_i}$ and $F_{X_j}$, there corresponds a unique bivariate cdf with uniform marginals $C : [0, 1]^2 \rightarrow [0, 1]$ called a copula, such that $F_{X_1, X_2}(x_1, x_2) = C(F_{X_1}(x_1), F_{X_2}(x_2))$ holds for all $(x_1, x_2) \in \mathbb{R}^2$ (Nelson, 1999). The MO copula is

$$C_{\theta_1, \theta_2}(u_1, u_2) = u_1^{1-\theta_1}u_2^{1-\theta_2}\min\{u_1^{\theta_1}, u_2^{\theta_2}\},$$

for $0 < \theta_1 < 1$ and $0 < \theta_2 < 1$. Using $U_i = F_{X_i}(x_i)$ where $X_i$ is EEW($a_i + a_3, \lambda, \xi$) and $\theta_i = \frac{a_3}{a_i + a_3}$, $i = 1, 2, 3$, gives the same joint cdf $F_{X_1, X_2}$ as (7).

The following result will provide explicitly the absolute continuous part and the singular part of the BEEW cdf.

**Theorem 2.4.** If $(X_1, X_2) \sim \text{BEWeW}(a_1, a_2, a_3, \lambda, \xi)$, then

$$F_{X_1, X_2}(x_1, x_2) = \frac{a_1 + a_2}{a_1 + a_2 + a_3}F_a(x_1, x_2) + \frac{a_3}{a_1 + a_2 + a_3}F_s(x_1, x_2),$$

where for $x = \min \{x_1, x_2\}$,

$$F_a(x_1, x_2) = (1 - e^{-\lambda H(x_3)})^{a_1 + a_2 + a_3},$$

and

$$F_s(x_1, x_2) = \frac{a_1 + a_2 + a_3}{a_1 + a_2} \left(1 - e^{-\lambda H(x_1)}\right)^{a_1 + a_2 + a_3}. \left(1 - e^{-\lambda H(x_2)}\right)^{a_3}$$

here $F_a(\cdot, \cdot)$ and $F_s(\cdot, \cdot)$ are the singular and the absolute continuous parts, respectively.

**Proof.** To find $F_a(x_1, x_2)$ from $F_{X_1, X_2}(x_1, x_2) = aF_a(x_1, x_2) + (1 - a)F_s(x_1, x_2)$, $0 \leq a \leq 1$, we compute

$$\frac{\partial^2 F_{X_1, X_2}(x_1, x_2)}{\partial x_1 \partial x_2} = a f_a(x_1, x_2)$$

from which $a$ may be obtained as

$$a = \int_0^\infty \int_0^{x_2} f_1(x_1, x_2) \, dx_1 dx_2 + \int_0^\infty \int_0^{x_1} f_2(x_1, x_2) \, dx_2 dx_1 = \frac{a_1 + a_2}{a_1 + a_2 + a_3},$$

and

$$F_a(x_1, x_2) = \int_0^{x_1} \int_0^{x_2} f_a(s, t) \, ds dt.$$ Once $a$ and $F_a(\cdot, \cdot)$ are determined, $F_s(\cdot, \cdot)$ can be obtained by subtraction. \qed

**Corollary 2.** The joint pdf of $X_1$ and $X_2$ can be written as follows for $x = \min \{x_1, x_2\};$

$$f_{X_1, X_2}(x_1, x_2) = \frac{a_1 + a_2}{a_1 + a_2 + a_3} f_a(x_1, x_2) + \frac{a_3}{a_1 + a_2 + a_3} f_s(x),$$

where

$$f_a(x_1, x_2) = \frac{a_1 + a_2 + a_3}{a_1 + a_2} \times \left\{ \begin{array}{ll} d_1 & \text{if } x_1 < x_2, \\ d_2 & \text{if } x_1 > x_2, \end{array} \right.$$ and

$$d_1 = f_{\text{EEW}}(x_1; a_1 + a_3, \lambda, \xi) f_{\text{EEW}}(x_2; a_2, \lambda, \xi),$$

$$d_2 = f_{\text{EEW}}(x_1; a_1, \lambda, \xi) f_{\text{EEW}}(x_2; a_2 + a_3, \lambda, \xi),$$

$$f_s(x) = f_{\text{EEW}}(x; a_1 + a_2 + a_3, \lambda, \xi).$$

Clearly, here $f_a(x_1, x_2)$ and $f_s(x)$ are the absolute continuous part and singular part, respectively.
Having obtained the marginal pdf of $X_1$ and $X_2$, we can now derive the pdf’s as presented in the following theorem.

**Theorem 2.5.** The conditional pdf of $X_i$ given $X_j = x_j$, denoted by $f_{X_i|X_j}(x_i|x_j)$, $i \neq j = 1, 2$, is given by

$$f_{X_i|X_j}(x_i|x_j) = \begin{cases} f_{X_i,X_j}^{(1)}(x_i,x_j) & \text{if } 0 < x_i < x_j \\ f_{X_i,X_j}^{(2)}(x_i,x_j) & \text{if } 0 < x_j < x_i \\ f_{X_i|X_j}^{(3)}(x_i|x_j) & \text{if } x_i = x_j > 0, \end{cases}$$

(13)

where

$$f_{X_i,X_j}^{(1)}(x_i,x_j) = \frac{(a_i + a_3) a_j \lambda h(x_j \xi)}{(a_2 + a_3) \left(1 - e^{-\lambda H(x_j \xi)}\right)^{a_3}} \times \left(1 - e^{-\lambda H(x_i \xi)}\right)^{a_i + a_3 - 1} e^{-\lambda H(x_i \xi)},$$

$$f_{X_i,X_j}^{(2)}(x_i,x_j) = a_i \lambda \rho(x_i \xi) \left(1 - e^{-\lambda H(x_i \xi)}\right)^{a_i - 1} \times e^{-\lambda H(x_i \xi)},$$

$$f_{X_i,X_j}^{(3)}(x_i|x_j) = \frac{a_3}{a_i + a_3} \left(1 - e^{-\lambda H(x_i \xi)}\right)^{a_i}.$$

**Proof.** The proof follows readily upon substituting the joint pdf of $(X_1, X_2)$ given in Theorem 2.2 and the marginal pdf of $X_i$, given in Theorem 2.3, using the following relation

$$f_{X_i|X_j}(x_i|x_j) = \frac{f_{X_i,X_j}(x_i,x_j)}{f_{X_i}(x_i)}, \quad i = 1, 2.$$  

(14)

**Proposition 1.** Since the joint sf and the joint cdf have the following relation

$$S_{X_1,X_2}(x_1,x_2) = 1 - F_{X_1}(x_1) - F_{X_2}(x_2) + F_{X_1,X_2}(x_1,x_2),$$

(15)

therefore, the joint sf of $X_1$ and $X_2$ also can be expressed in a compact form.

**Proposition 2.** Basu (1971) defined the bivariate failure rate function $h_{X_1,X_2}(x_1,x_2)$ for the random vector $(X_1, X_2)$ as the following relation

$$h_{X_1,X_2}(x_1,x_2) = \frac{f_{X_1,X_2}(x_1,x_2)}{S_{X_1,X_2}(x_1,x_2)}.$$  

(16)

We can obtain the bivariate failure rate function $h_{X_1,X_2}(x_1,x_2)$ for the random vector $(X_1, X_2)$ by substituting from (8) and (15) in (16).

**Lemma 1.** The cdf of $Y = \max\{X_1, X_2\}$ is given as

$$F_Y(y) = \left(1 - e^{-\lambda H(y \xi)}\right)^{a_1 + a_2 + a_3}.$$  

(17)

**Proof.** Since

$$F_Y(y) = P(Y \leq y) = P(\max\{X_1, X_2\} \leq y) = P(X_1 \leq y, X_2 \leq y) = P(\max\{U_1, U_3\} \leq y, \max\{U_2, U_3\} \leq y) = P(U_1 \leq y, U_2 \leq y, U_3 \leq y),$$

where the random variables $U_i$ $(i = 1, 2, 3)$ are mutually independent, we directly obtain the result.

**Lemma 2.** The cdf of $T = \min\{X_1, X_2\}$ is given as

$$F_T(t) = \left(1 - e^{-\lambda H(t \xi)}\right)^{a_1 + a_3} + \left(1 - e^{-\lambda H(t \xi)}\right)^{a_2 + a_3} - \left(1 - e^{-\lambda H(t \xi)}\right)^{a_1 + a_2 + a_3}.$$

**Proof.** It is easy to prove that by using Equations (15) and (17).

3. **Special cases**

In this Section, we consider some special cases of the BEEW distributions.

3.1 Bivariate generalized exponential distribution

If $H(x; \xi) = x$, then the joint cdf (7) becomes

$$F_{X_1,X_2}(x_1, x_2) = \begin{cases} b_1 & \text{if } x_1 \leq x_2 \\ b_2 & \text{if } x_1 > x_2, \end{cases}$$

where

$$b_1 = \left(1 - e^{-\lambda x_1}\right)^{a_1 + a_3} \left(1 - e^{-\lambda x_2}\right)^{a_2},$$

$$b_2 = \left(1 - e^{-\lambda x_1}\right)^{a_1} \left(1 - e^{-\lambda x_2}\right)^{a_2 + a_3},$$

which is the joint cdf of bivariate generalized exponential (BGE) distribution introduced by Kundu and Gupta (2009). By Theorem 12, the marginal distributions of $X_1$ and $X_2$ are GE($a_1 + a_3, \lambda$) and GE ($a_2 + a_3, \lambda$), respectively.

3.2 Bivariate generalized linear failure rate distribution

If $H(x; \xi) = \beta x + \frac{\gamma}{2} x^2$ and $\lambda = 1$, then the joint cdf (7) becomes

$$F_{X_1,X_2}(x_1, x_2) = \begin{cases} b_1 & \text{if } x_1 \leq x_2 \\ b_2 & \text{if } x_1 > x_2, \end{cases}$$

where

$$b_1 = \left(1 - e^{-\beta x_1 - \frac{\gamma}{2} x_1^2}\right)^{a_1 + a_3} \left(1 - e^{-\beta x_2 - \frac{\gamma}{2} x_2^2}\right)^{a_2},$$
where the random variables are GLFR and GE which is the joint cdf of bivariate generalized Gompertz distribution. By Theorem 12, the marginal distributions of $X_1$ and $X_2$ are EMWE $(a_1 + a_3, \lambda, \beta, \gamma)$ and EMWE $(a_2 + a_3, \lambda, \beta, \gamma)$, respectively.

3.6 Bivariate exponentiated modified Weibull extension distribution

If $H(x; \xi) = \beta(e^{x/\beta} - 1)$, then the joint cdf (7) becomes

$$F_{X_1, X_2}(x_1, x_2) = \begin{cases} b_1 & \text{if } x_1 \leq x_2, \\ b_2 & \text{if } x_1 > x_2, \end{cases}$$

where

$$b_1 = \left(1 - e^{-\lambda x_1^\alpha} \right)^{a_1} \left(1 - e^{-\lambda x_2^\alpha} \right)^{a_2},$$

$$b_2 = \left(1 - e^{-\lambda x_1^\alpha} \right)^{a_1} \left(1 - e^{-\lambda x_2^\alpha} \right)^{a_2 + a_3},$$

which is the joint cdf of bivariate exponentiated modified Weibull extension (BEMWE) distribution introduced by El-Gohary and El-Morshedy (2015). By Theorem 12, the marginal distributions of $X_1$ and $X_2$ are EMWE $(a_1 + a_3, \lambda, \beta, \gamma)$ and EMWE $(a_2 + a_3, \lambda, \beta, \gamma)$, respectively.

4 Maximum likelihood estimation

In this section, we first study the maximum likelihood estimations (MLE’s) of the parameters. Then, we propose an Expectation-Maximization (EM) algorithm to estimate the parameters.

Let $(x_{11}, x_{12}, \ldots, x_{1n}, x_{2n})$ be an observed sample with size $n$ from BEEW distribution with parameters $\Theta = (a_1, a_2, a_3, \lambda, \beta, \xi)$. Also, consider

$$I_0 = \{ i : x_{1i} = x_{2i} \}, \quad I_1 = \{ i : x_{1i} < x_{2i} \},$$

$$I_2 = \{ i : x_{1i} > x_{2i} \}, \quad i = 1, \ldots, n,$$

and

$$n_0 = |I_0|, \quad n_1 = |I_1|, \quad n_2 = |I_2|, \quad n = n_0 + n_1 + n_2.$$ 

Therefore, the log-likelihood function can be written as

$$\ell(\Theta) = \sum_{i \in I_1} \log(f_1(x_{1i}, x_{2i})) + \sum_{i \in I_2} \log(f_2(x_{1i}, x_{2i})) + \sum_{i \in I_0} \log(f_0(x_i))$$
Weibull extension (BEMWE) distribution introduced by which is the joint cdf of bivariate exponentiated gen-

\[ \hat{\lambda}_3(\lambda) = \frac{n_0 + n_2n_1 + v_2n_2}{\sum_{i \in b} W(x_i) + \sum_{i \in l} W(x_{ii}) + \sum_{i \in l_2} W(x_{i2})'} \]

where \( W(x) = \log \left( 1 - e^{-\lambda H(x;i)} \right) \). For fixed \( a_1, a_2, a_3 \) and \( \xi, \ell_{\text{pseudo}}(\Theta) \) is maximized with respect to \( \lambda \) as a solution of the following equation:

\[ \frac{n_0 + 2n_1 + 2n_2}{g(\lambda)} = \lambda, \]

where

\[ g(\lambda) = -(a_1 + a_2 + a_3 - 1) \sum_{i \in b} H(x_i; \xi) \frac{e^{-\lambda H(x_i; \xi)}}{1 - e^{-\lambda H(x_i; \xi)}} \]

\[ - (a_1 + a_3 - 1) \sum_{i \in l} H(x_{ii}; \xi) e^{-\lambda H(x_{ii}; \xi)} \]

\[ - (a_2 + a_3 - 1) \sum_{i \in l_2} H(x_{i2}; \xi) e^{-\lambda H(x_{i2}; \xi)} \]

\[ - (a_2 - 1) \sum_{i \in l_1} H(x_{i2}; \xi) e^{-\lambda H(x_{i2}; \xi)} \]

\[ - (a_1 - 1) \sum_{i \in l_2} H(x_{i1}; \xi) e^{-\lambda H(x_{i1}; \xi)} \]

\[ + \sum_{i \in b} H(x_i; \xi) + \sum_{i \in l_1 \cup l_2} H(x_{ii}; \xi) \]

\[ + \sum_{i \in l_1 \cup l_2} H(x_{i2}; \xi). \]

Finally, for fixed \( a_1, a_2, a_3 \) and \( \lambda, \ell_{\text{pseudo}}(\Theta) \) is maximized with respect to \( \xi \) as a solution of the following equation:

\[ \frac{\partial}{\partial \xi} \ell_{\text{pseudo}}(\Theta) = 0. \]

The following steps can be used to compute the MLE’s of the parameters via the EM algorithm:

**Step 1:** Take some initial value of \( \Theta \), say \( \Theta^{(0)} = (a_1^{(0)}, a_2^{(0)}, a_3^{(0)}, \lambda^{(0)}, \xi^{(0)})' \).

**Step 2:** Compute \( u_1, u_2, v_1, \) and \( v_2 \).

**Step 3:** Find \( \hat{\lambda} \) by solving the equation (22), say \( \hat{\lambda}^{(1)} \).

**Step 4:** Find \( \hat{\xi} \) by solving the equation (23), say \( \hat{\xi}^{(1)} \).

**Step 5:** Compute \( \hat{a}_i^{(1)} = \hat{a}_i(\hat{\lambda}^{(1)}, \hat{\xi}^{(1)}), i = 1, 2, 3 \) from (19)-(21).

**Step 6:** Replace \( \Theta^{(0)} \) by \( \Theta^{(1)} = (\hat{a}_1^{(1)}, \hat{a}_2^{(1)}, \hat{a}_3^{(1)}, \hat{\lambda}^{(1)}, \hat{\xi}^{(1)})' \), go back to step 1 and continue the process until convergence take place.

## 5 Two real examples

We consider BEEW distributions for fitting these two data sets. But, this family of distributions is a large class of distributions. Here, we consider six sub-models of BEEW distributions: BGE, BGLFR, BEW, BGG, BEGWG, and BEMWE. Some of them are suggested in literature.

Using the proposed EM algorithm, these models are fitted to the bivariate data set, and the MLE’s and their corresponding log-likelihood values are calculated. The standard errors (s.e.) based on the observed information matrix are obtained.

For each fitted model, the Akaike Information Criterion (AIC), the corrected Akaike information criterion (AICC) and the Bayesian information criterion (BIC) are calculated. We also obtain the Kolmogorov-Smirnov (K-S) distances between the fitted distribution, the empirical distribution function, and the corresponding p-values (in parenthesis) for \( X_1, X_2 \) and \( \max(X_1, X_2) \). For more information about this criteria of model selection, we refer the reader to Burnham and Anderson (1998) and Sullivan and Joyce (2005) Finally, we make use the likelihood ratio test (LRT) and the corresponding p-values for testing the BGE against other models.

**Example 1.** The data set is given from Meantinis (2007) and is obtained from the group stage of the UEFA Champion’s League for the years 2004-05 and 2005-2006. In addition, Kundu and Gupta (2009) and Sarhan et al. (2011) analyzed this data. The data represent the football (soccer) data where at least one goal scored by the home team and at least one goal scored directly from a kick goal (like penalty kick, foul kick or any other direct kick) by any team have been considered. Here \( X_1 \) represents the time in minutes of the first kick goal scored by any team and \( X_2 \) represents the first goal of any type scored by the home team.

In Table 2 we provide the MLEs of the unknown parameters of six sub models of BEEW distributions. We have also included the AIC, AICC, and BIC values for model selection purposes. From this data, we find the values of the all unknown parameters with its standard errors and the log-likelihood for the six models. Using the EM algorithm we obtain the MLEs of all parameters. By substituting the MLE of unknown parameters, we get the estimation of the variance covariance matrix. The likelihood ratio test statistic and the associated p values for marginal distributions showed that all marginal distributions provide significant fit to this data. It is clear that all six models are appropriate for this data set but among these all six models, the BEW and BGG models are preferable, on the basis of both AIC, AICC, and BIC values. The AIC, AICC, and BIC values for BEW (BGG) models are 593.361 (593.710), 595.297 (595.646), and 601.416 (601.765), respectively.

**Example 2.** The data set was first published in ‘Washington Post’ and is available in Csörgö and Welsh (1989). It is represent the American Football League for the matches on three consecutive weekends in 1986. Here, \( X_1 \) represents the ‘game time’ to the first points scored by kicking the ball between

</table>

Table 3 displays the MLE’s of the parameters (with corresponding standard errors in parentheses) for the bivariate distributions which are obtained by the EM algorithm given in Section 4. To test the goodness-of-fit of the marginal distributions, we calculated the Kolmogorov - Smirnov (K-S) statistic with its respective p-value. From K-S in this table, it can be concluded that all marginal distributions of six models are appropriate for this data set. Since the values of the AIC (−65.340), BIC (−64.258), and AICC (−58.389) are smaller for the BGE distribution compared with those values of the other models, this bivariate distribution seems to be a very competitive model for these data.
Table 3: The MLE’s, log-likelihood, AIC, AICC, BIC, K-S, and LRT statistics for six sub-models of BEEW distribution of second data set.

6 Conclusions

In this paper we have introduced the new bivariate exponentiated extended Weibull distribution whose marginal are exponentiated extended Weibull distributions. It contains a number of known special submodels (at least 46 bivariate distributions) such as bivariate generalized exponential, bivariate generalized linear failure rate, bivariate exponentiated Weibull, bivariate generalized Gompertz, and bivariate exponentiated modified Weibull extension distributions, among others. We think the formulas derived are manageable by using modern computer resources with analytic and numerical capabilities. The proposed bivariate model has a singular distribution, and it can be used quite effectively instead of the Marshall-Olkin bivariate exponential model or the bivariate generalized exponential model when there are ties in the data. This new bivariate distribution has several interesting properties and it can be used as an alternative to the several bivariate distributions. The generation of random samples from proposed bivariate distribution is very simple, and therefore Monte Carlo simulation can be performed very easily for different statistical inference purpose. Maximum likelihood estimates of the new bivariate model are discussed. It may be mentioned that an EM algorithm along the same lines as the bivariate case may be developed. Alternatively, using the copula structure, other estimators may be used and their properties can be established. Analyses of two real data sets indicate the good performance and usefulness of the new model.
Acknowledgments

The authors wish to thank the Editor and two anonymous referees for their careful reading and some constructive criticism on the earlier draft of the paper. The authors are also thankful to the Yazd University for supporting this research.
